

Linear Algebra: Unit II - Review of Main Topics

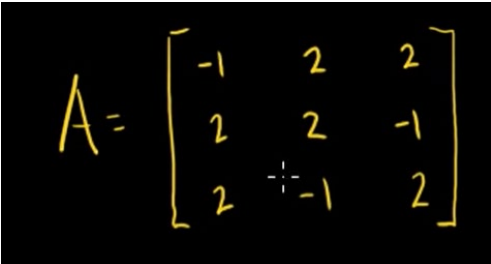

✓ Characteristic Polynomial

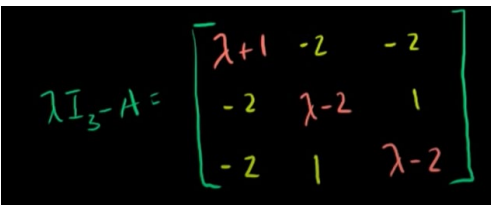

- The characteristic polynomial $\det(A - \lambda I_n)$ of an $n \times n$ matrix, whose roots are the eigenvalues of A . Computation of eigenvectors, determining diagonalizability.

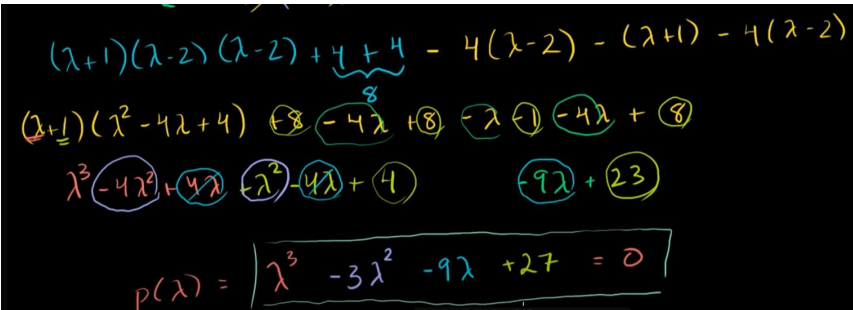

- Definition:**

- This is the matrix that you get by subtracting λ from the diagonal of a matrix

- Example:**

1. 
$$A = \begin{bmatrix} -1 & 2 & 2 \\ 2 & 2 & -1 \\ 2 & -1 & 2 \end{bmatrix}$$

2. 
$$\lambda I_3 - A = \begin{bmatrix} \lambda+1 & -2 & -2 \\ -2 & \lambda-2 & 1 \\ -2 & 1 & \lambda-2 \end{bmatrix}$$

3. 
$$\begin{aligned} & (\lambda+1)(\lambda-2)(\lambda-2) + 4 + 4 - 4(\lambda-2) - (\lambda+1) - 4(\lambda-2) \\ & (\lambda+1)(\lambda^2 - 4\lambda + 4) + 8 - 4\lambda + 8 - \lambda - 1 - 4\lambda + 8 \\ & \lambda^3 - 4\lambda^2 + 4\lambda + \lambda^2 - 4\lambda + 4 - 9\lambda + 23 \\ & p(\lambda) = \lambda^3 - 3\lambda^2 - 9\lambda + 27 = 0 \end{aligned}$$

- Links:**

- [Khan Academy Eigen values of 3x3 matrix](#)
- [Eigenvalue and vector solver with steps](#)
- [Quiz 13, Q1 Example](#)

✓ Coordinate Vectors

- **Definition:**

1. Coordinate vectors $[\mathbf{v}]_S$ with respect to some ordered basis $S = \{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k\}$ of a subspace of \mathbb{R}^n .

2.
$$[\vec{w}]_S = \begin{bmatrix} \vec{w} \cdot \vec{v}_1 \\ \vdots \\ \vec{w} \cdot \vec{v}_k \end{bmatrix} \quad \text{if } S = \{\vec{v}_1, \dots, \vec{v}_k\}$$

- **Links:**

1. [Page 9 lecture notes](#)
2. [Coordinate Vectors – Khan Academy](#)

✓ Transition matrices

- **Definition:**

1. Transition matrices: $P_{S \leftarrow T} [\mathbf{v}]_T = [\mathbf{v}]_S$ for all vectors \mathbf{v} in the subspace. We have $P_{T \leftarrow S} = P_{S \leftarrow T}^{-1}$

- **Links:**

1. [Transition Matrices – Khan Academy](#)

✓ Vector Lengths, distances, and angles

- Lengths, distances, and angles of vectors in terms of the dot product in \mathbb{R}^n . Orthogonality of vectors and of subspaces; orthonormal = orthogonal and unit vectors.

- **Definition:**

1.
$$\begin{array}{ll} \text{length} & \|\vec{v}\| = \sqrt{\vec{v} \cdot \vec{v}} \\ \text{distance} & \|\vec{v} - \vec{w}\| \\ \text{angle} & \vec{v} \cdot \vec{w} = \|\vec{v}\| \|\vec{w}\| \cos \theta \end{array}$$

- **Links:**

1. [Quiz 10 Answers and Submission for Angle and Distance between vectors](#)

✓ Orthogonal projection onto a subspace (shorter Gram-Schmidt Alg.)

- **Definition:**

1. Orthogonal *projection* onto a subspace W - is the closest vector in W to a given vector. Computed in terms of an orthogonal/orthonormal basis.

2. Projection of v onto w below:

$$\text{proj}_w(v) = \sum_{j=1} \left(\frac{v \cdot w_j}{w_j \cdot w_j} \right) \cdot w_j$$

3. Definition of **Orthogonality**:

- if two vectors dotted together equal zero (0);
- same is true for $v^T w$ dotted equal zero (0). This means that the two vectors meet at a *right angle*;
- If v_i through v_j any v_i or v_j dotted equal zero are **pairwise orthogonal**

4. Definition of **Orthonormal**

- If v_i through v_j any v_i or v_j dotted equal zero AND v_i is a *unit vector*.

- **Example:**

1.

- **Links:**

1. [Quiz 11 \(Q1\) Answers and Submission for Orthogonal Projection](#)
2. [Page 16 Lecture Notes](#)

✓ Gram-Schmidt algorithm

- **Definition:**

$$\begin{aligned}\vec{v}_1 &= \vec{w}_1, & \vec{v}_2 &= \vec{w}_2 - \left(\frac{\vec{w}_2 \cdot \vec{v}_1}{\vec{v}_1 \cdot \vec{v}_1} \right) \vec{v}_1, \\ \vec{v}_3 &= \vec{w}_3 - \left(\frac{\vec{w}_3 \cdot \vec{v}_1}{\vec{v}_1 \cdot \vec{v}_1} \right) \vec{v}_1 - \left(\frac{\vec{w}_3 \cdot \vec{v}_2}{\vec{v}_2 \cdot \vec{v}_2} \right) \vec{v}_2\end{aligned}$$

1.

- **Example:**

Example Find an orthogonal basis for W ,

The subspace of \mathbb{R}^4 spanned by

$$\vec{w}_1 = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 0 \end{bmatrix}, \quad \vec{w}_2 = \begin{bmatrix} -1 \\ 0 \\ -1 \\ 0 \end{bmatrix}, \quad \vec{w}_3 = \begin{bmatrix} -1 \\ 0 \\ 0 \\ -1 \end{bmatrix}.$$

Gram-Schmidt! $\vec{v}_1 = \vec{w}_1$

$$\begin{aligned}\vec{v}_2 &= \vec{w}_2 - \left(\frac{\vec{w}_2 \cdot \vec{v}_1}{\vec{v}_1 \cdot \vec{v}_1} \right) \vec{v}_1 = \begin{bmatrix} -1 \\ 0 \\ -1 \\ 0 \end{bmatrix} - \frac{-2}{3} \begin{bmatrix} 1 \\ 1 \\ 1 \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} -1/3 \\ 2/3 \\ -1/3 \\ 0 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} -1 \\ 2 \\ -1 \\ 0 \end{bmatrix} \quad \text{note this is orthogonal to } \vec{v}_1 = \vec{w}_1.\end{aligned}$$

$$\begin{aligned}\vec{v}_3 &= \vec{w}_3 - \left(\frac{\vec{w}_3 \cdot \vec{v}_1}{\vec{v}_1 \cdot \vec{v}_1} \right) \vec{v}_1 - \left(\frac{\vec{w}_3 \cdot \vec{v}_2}{\vec{v}_2 \cdot \vec{v}_2} \right) \vec{v}_2 \\ &= \begin{bmatrix} -1 \\ 0 \\ 0 \\ -1 \end{bmatrix} - \frac{-1}{3} \begin{bmatrix} 1 \\ 1 \\ 1 \\ 0 \end{bmatrix} - \frac{1}{6} \begin{bmatrix} -1 \\ 2 \\ -1 \\ 0 \end{bmatrix} = \begin{bmatrix} -1/2 \\ 0 \\ 1/2 \\ -1 \end{bmatrix} \quad \text{this is orth. to } \vec{v}_1, \vec{v}_2.\end{aligned}$$

- **Links:**

1. [Page 12 Lecture Notes](#)
2. [Quiz 10 \(Q2\) Answers and Submission for Gram-Schmidt Algorithm](#)

✓ Orthogonal complements

- **Definition:**

1. **Formal Definition:**

- W^\perp is the subspace of all vectors that are orthogonal to W .
- Every vector \mathbf{v} in \mathbb{R}^n can be decomposed into the sum of its projection to W and its projection to W^\perp .

2. **Simple Definition**

- The orthonormal basis for W^\perp is the orthogonal complement
- if $\mathbf{v} \cdot \mathbf{w} = 0$, and w is a subspace that contains v , v is orthogonal to w .
- W^\perp is all of the vectors that are orthogonal to w , which is itself a *subspace*

- **Example:**

- **Links:**

1. [Page 13 Lecture Notes](#)
2. [Quiz 11 \(Q2\) Answers for computing the Orthogonal Complement](#)

✓ Least Squares

- **Definition:**

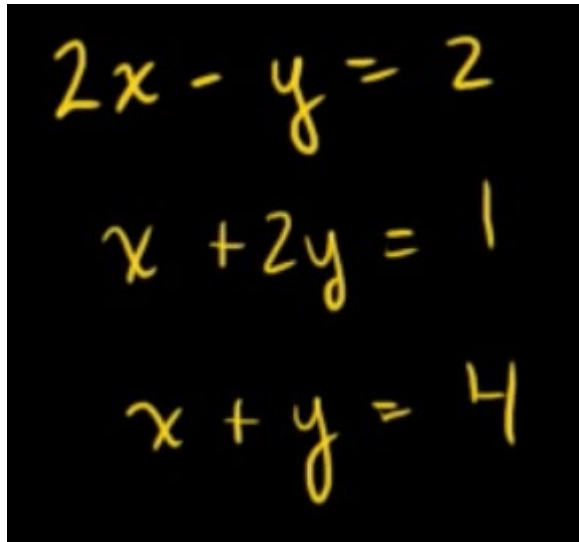

1. If $A\mathbf{x} = \mathbf{b}$ is an *inconsistent system*, solving $A^T A\mathbf{x} = A^T \mathbf{b}$ minimizes the length through $\|A\mathbf{x} - \mathbf{b}\|$.
2. "Sum of Squares"

the unique L.S. solution is $\vec{x} = (A^T A)^{-1} A^T \vec{b}$

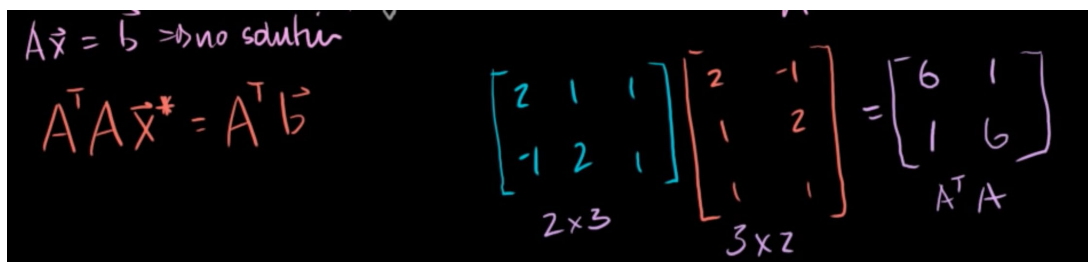

This matrix represents a projection onto the column space of A

- **Example:**

1. Equations

$$\begin{aligned} 2x - y &= 2 \\ x + 2y &= 1 \\ x + y &= 4 \end{aligned}$$

2. Least Squares

$$\begin{aligned} A\vec{x} &= \vec{b} \Rightarrow \text{no solution} \\ A^T A \vec{x}^* &= A^T \vec{b} \end{aligned}$$
$$\begin{matrix} \begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \\ 2 \times 3 \end{matrix} \begin{matrix} \begin{bmatrix} 2 \\ -1 \end{bmatrix} \\ 2 \times 1 \end{matrix} = \begin{matrix} \begin{bmatrix} 6 & 1 \end{bmatrix} \\ A^T A \end{matrix}$$

$$\begin{matrix} & 3 \times 2 \\ \begin{bmatrix} 2 & 1 & 1 \\ -1 & 2 & 1 \end{bmatrix} & \begin{bmatrix} 2 \\ 1 \\ 4 \end{bmatrix} & = & \begin{bmatrix} 4+1+4 \\ -2+2+4 \end{bmatrix} = \begin{bmatrix} 9 \\ 4 \end{bmatrix} \\ 2 \times 3 & 3 \times 1 & & \end{matrix}$$

3. Find Solution

$$\begin{aligned} \underline{A^T A} \vec{x}^* &= A^T \vec{b} \\ \begin{bmatrix} 6 & 1 \\ 1 & 6 \end{bmatrix} \vec{x}^* &= \begin{bmatrix} 9 \\ 4 \end{bmatrix} \\ \hookrightarrow \begin{bmatrix} 6 & 1 & | & 9 \\ 1 & 6 & | & 4 \end{bmatrix} \\ \downarrow \\ \begin{bmatrix} 1 & 6 & | & 4 \\ 6 & 1 & | & 9 \end{bmatrix} & \quad 9-24 \end{aligned}$$

$$\begin{aligned} \begin{bmatrix} 1 & 6 & | & 4 \\ 0 & -35 & | & -15 \end{bmatrix} &\rightarrow \begin{bmatrix} 1 & 6 & | & 4 \\ 0 & 1 & | & \frac{3}{7} \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & | & \frac{10}{7} \\ 0 & 1 & | & \frac{3}{7} \end{bmatrix} \\ \vec{x}^* &= \begin{bmatrix} \frac{10}{7} \\ \frac{3}{7} \end{bmatrix} \end{aligned}$$

2. [Least Squares Khan Academy – Minute 5:00](#)

✓ QR Factorization

- **Definition:**

1. Want least squares solution having orthonormal columns

- **Links:**

1. [Page 51 Lecture Notes](#)
2. [Quiz 12 \(Q1\) Answers for QR Factorization Computation](#)

✓ Spectral Decomposition: $P^T A P$

- **Definition:**

- If $A = A^T$, then A is diagonalizable and has real eigenvalues. The eigenspaces corresponding to *distinct* eigenvalues are automatically orthogonal. We can find a matrix P so that $P^T = P^{-1}$ and $P^T A P$ is diagonal. Moreover, if $\{v_1, \dots, v_n\}$ form an orthonormal basis for \mathbb{R}^n composed of eigenvectors of A , then $A = \sum_{i=1}^n \lambda_i (v_i v_i^T)$; this is a spectral decomposition of A

- **Links:**

1. [Quiz 12 \(Q2\) Answers for Spectral Decomposition Computation](#)

✓ Quadratic Forms

- Quadratic forms = functions of the form $q(\mathbf{v}) = \mathbf{v}^T A \mathbf{v}$ for some symmetric matrix A . Positive definite/semidefinite quadratic forms (or symmetric matrices) = those associated to A with all eigenvalues positive/nonnegative. Quadrics = equations of the form $q(\mathbf{v}) = c$ for some real number c . These can be studied effectively by diagonalizing A .

- **Definition:**

1. Form Matrix:

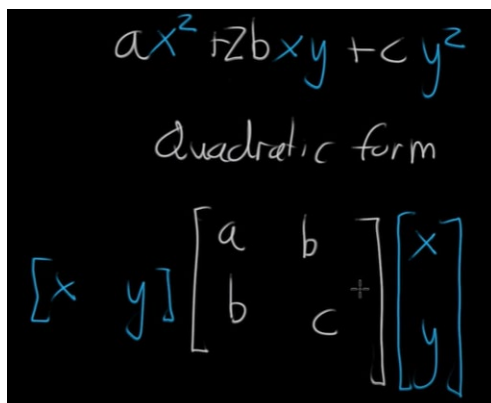

- $A_{ij} = \frac{b_{ij} + b_{ji}}{2}$

2. Every variable in the equation is a quadratic expression, no constants etc

- **Example:**

1. Notation of Quadratic Forms:

- Setup

Handwritten notes on a blackboard showing the quadratic form equation and its matrix notation:

$$ax^2 + 2bxy + cy^2$$

quadratic form

$$\begin{bmatrix} x & y \end{bmatrix} \begin{bmatrix} a & b \\ b & c \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

- Multiply right hand two matrices

$$\begin{bmatrix} x & y \end{bmatrix} \begin{bmatrix} a & b \\ b & c \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

$$\begin{bmatrix} x & y \end{bmatrix} \begin{bmatrix} ax + by \\ bx + cy \end{bmatrix}$$

- Multiply left hand two

$$x(ax + by) + y(bx + cy)$$

$$ax^2 + 2bxy + cy^2$$

- **Key:** You end up with the *same equation that you started with*

2. Example 3 x 3 Matrix

$$\begin{bmatrix} x & y & z \end{bmatrix} \begin{bmatrix} a & b & c \\ b & d & e \\ c & e & f \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

3. In Class Example

Exercise

In general, let $a_{ij} = \frac{b_{ij} + b_{ji}}{2}$ and set

$$A = \begin{bmatrix} a_{11} & \dots & a_{1n} \\ \vdots & & \vdots \\ a_{n1} & \dots & a_{nn} \end{bmatrix} \text{ then } A = A^T \text{ and}$$

$$q(\vec{v}) = \vec{v}^T A \vec{v}$$

Ex $q(x_1, x_2, x_3) = x_1 x_2 + x_2 x_3 - 5x_1 x_3 =$

if $A = \begin{bmatrix} 0 & 1/2 & -5/2 \\ 1/2 & 0 & 1/2 \\ -5/2 & 1/2 & 0 \end{bmatrix} \quad [x_1 \ x_2 \ x_3] A \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$

• Links:

1. [Khan Academy – Keys to Expressing quadratic form via Matrix Notation](#)
2. [Eigenvalue and eigenvector calculator](#)

✓ Singular Value Decomposition (SVD)

- **Definition:**

1. Singular Value Decompositions: if A is an $m \times n$ matrix, then $A = V \Sigma U^T$ where U is an $n \times n$ matrix with orthonormal columns which are eigenvectors of $A^T A$. The nonzero entries in Σ occur along its “diagonal” and are the square roots of the eigenvalues of $A^T A$; these are the (nonzero) singular values of A . The first $r = \dim C(A)$ columns of V are determined by the conditions $A \mathbf{u}_i = \sigma_i \mathbf{v}_i$. The remaining $m - r$ columns are any orthonormal basis of $N(A^T)$.
2.

Formula for SVD: $A = V \Sigma U^T$

- **Example:**

1. Goal: Compute $A = V \Sigma U^T$
2. Steps (See Pseudoinverses/In Class Examples)

- **Solve for “U”**

- i. $A^T A$
- ii. Get Eigenvalues
- iii. Get Eigenvectors
- iv. Put eigenvectors in matrix form $[\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \dots, \mathbf{v}_k]$ and multiply by $\frac{1}{\sqrt{\text{contents}^2}}$

- **Solve for “Σ”**

- i. Put square root of eigenvalues in RREF form, e.g. have the eigenvalues be the leading ones of identity

$$\bullet \Sigma = \begin{bmatrix} \sqrt{\text{eigen}_1} & 0 \\ 1 & \sqrt{\text{eigen}_2} \end{bmatrix}$$

- **Solve for “V”**

- i. Eigenvector 1, the rest of the matrix are 0's because they will be killed off anyways

- **Links:**

1. [In class Example – SVD and Pseudoinverse – start at beginning of video](#)
2. [Quiz 13 Solutions](#)
3. Also see video lecture (*not posted yet*) for Quiz 13 Solutions

✓ Pseudoinverses

• Definition:

1. Pseudoinverses: if $A = V\Sigma U^T$ is an SVD of A , then its pseudoinverse has SVD $\tilde{A} = U\tilde{\Sigma}V^T$, where $\tilde{\Sigma}$ is the transpose of Σ with each (positive) σ_i replaced by $1/\sigma_i$.

2. Formula of Pseudoinverse: $\tilde{A} = U\tilde{\Sigma}V^T$

• Uses:

1. Compute a "best fit" (least squares) solution to a system of linear equations that *lacks a unique solution*

• Example:

1. In Class Examples

Ex Compute pseudo inverse of

$$A = \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix}. \quad \text{Need SVD of } A.$$

(Note if columns or rows of A are lin. ind., then there's a much faster way to find \tilde{A}).

$$A^T A = \begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ 4 & 8 \end{bmatrix}$$

$$\lambda = 15 \quad \tilde{u}_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix} \frac{1}{\sqrt{5}}$$

$$\lambda = 0 \quad \tilde{u}_2 = \begin{bmatrix} 2 \\ -1 \end{bmatrix} \frac{1}{\sqrt{5}}$$

$$U = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}$$

$$A\tilde{u}_1 = \begin{bmatrix} 3 \\ 3 \end{bmatrix} \frac{1}{\sqrt{5}} = \frac{\sqrt{25}}{\sqrt{5}} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \frac{1}{\sqrt{5}} = \sqrt{5} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \frac{1}{\sqrt{5}} = \sigma_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} \frac{1}{\sqrt{5}} = \sigma_1 \tilde{v}_1$$

$$\Sigma = \begin{bmatrix} \sqrt{5} & 0 \\ 0 & 0 \end{bmatrix} \quad A\tilde{u}_2 = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$V = [\tilde{v}_1 \quad \tilde{v}_2 \quad \tilde{v}_3] \quad \text{where } \tilde{v}_2, \tilde{v}_3 \text{ are orthogonal unit vectors, orthogonal to } \tilde{v}_1. \\ \text{(won't actually matter for } \tilde{A}, \text{ as we'll see.)}$$

So $A = V\Sigma U^T$, in fact $A = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} \sqrt{5} & 0 \\ 0 & 0 \end{bmatrix} \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}$

and $\tilde{A} = U\tilde{\Sigma}V^T$ where $\tilde{\Sigma} = \begin{bmatrix} 1/\sqrt{5} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$

$$= \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix} \begin{bmatrix} 1/\sqrt{5} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1/\sqrt{5} & 1/\sqrt{5} & 1/\sqrt{5} \\ \tilde{v}_2^T \\ \tilde{v}_3^T \end{bmatrix}$$

$$= \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix} \begin{bmatrix} 1/\sqrt{5} & 1/\sqrt{5} & 1/\sqrt{5} \\ 0 & 0 & 0 \end{bmatrix} \quad 5 \cdot 45 = 15^2$$

$$= \begin{bmatrix} \frac{1}{15} & \frac{1}{15} & \frac{1}{15} \\ \frac{2}{15} & \frac{2}{15} & \frac{2}{15} \end{bmatrix} = \frac{1}{15} A^T \quad (\tilde{A} \text{ is not always a multiple of } A^T)$$

Note $A\tilde{A} = \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \end{bmatrix} \frac{1}{15} = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \end{bmatrix} \frac{1}{3} = \text{proj}_{C(A)}$

i.e. if $\begin{bmatrix} x \\ y \\ z \end{bmatrix}$ in \mathbb{R}^3 , the closest vector to it in $C(A)$

$$\text{is } A\tilde{A} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \frac{1}{3} (x+y+z) \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

• Links:

1. [In class Example – SVD and Pseudoinverse – start at beginning of video](#)

4. [Pseudoinverse Calculator](#)

√ Generalized Eigenvectors

- **Definition:**

1. Take the determinant of a matrix to get the $(A - \lambda)$
2. The result from raising to exponent m is equal to 0
3. However, the result from raising to exponent $m - 1$ is **not** equal to 0

- **Uses:**

1. Calculating exponential matrices

- **Example:**

- 1.

- **Links:**

1. [Page 115 Lecture Notes](#)
2. [Quiz 14 Answers \(Page 147 Lecture Notes\)](#)

√ Exponential Matrices

- **Definition:**

1. e^A

- **Uses:**

1. Infinite series, like geometric series $[1/(1 + r)]$
2. Differential Equations

- **Example:**

1. Basic Examples ([Page 121 Lecture Notes](#))

- **Links:**

1. [Page 119 Lecture Notes](#)

√ Jordan Canonical Form (aka Jordan Normal Form)

- **Definition:**

1. The Jordan form of a matrix generalizes diagonalization and If A is not diagonalizable "As Jordan form is "as close as possible" to being diagonal.
2. The idea will be to find a good basis of generalized eigenvector so if p is the matrix with them as columns then $P^{-1}AP$ will be the Jordan form.

- **Uses:**

1. [Page 143 Lecture Notes](#)

- **Example:**

1. Compute Jordan Form without computing (knowing) P ([Page 149 Lecture Notes](#))

- **Links:**

1. [Page 135 Lecture Notes](#)

Relevant/Useful/Important Theorems:

Diagonalizable Properties

- If A is a square matrix with n distinct eigenvalues, it is diagonalizable (the converse is false).

Eigenvectors and Linear Independence

- The eigenvectors of a matrix A associated to different eigenvalues are automatically linearly independent (and if A is symmetric then they are orthogonal).

Characteristic Polynomial and Similar Matrices

- if A and B are similar matrices (meaning $B = P^{-1}AP$ for some nonsingular matrix P), then they have the same characteristic polynomial (the converse is false).
